Received May 21, 2001

Abstract pression of Chalcone synthase A is a key enzyme in the anthocyanin biosynthesis pathway. Ex-

gene in transgenic

Petunia hybrida

resulted in flower color alterations and

co-suppression of transgenes and endogenous genes. We fused the

-glucuronidase (

uidA) gene

to the C-terminal of

gene, and transferred the fusion gene into

Pétunia hybrida

via Agrobac-

terium tumefaciens.

GUS histochemical staining analysis showed that co-our previon occurred

specifically during the development of flowers and co-suppression required the mutual interaction

of endogenous genes and transgenes. RNA

hybridization analysis suggested that

co-suppression occurred in the entire plant, and RNA degradation occurred in the cytoplasm.

Keywords: chalcone synthase A, co-suppression,

Petunia hybrida

, in situ hybridization.

Over the last decade, a large number of transgenic plants have been generated to modify or improve different traits of crops. Unexpectedly, in some cases when the transgene is homologous. to an endogenous gene, the expression of both the transgene and the endogenous gene may be

come co suppressed which is called the co-suppression phenomenon

Co-suppression has been

observed in many kinds of plants, even in bacteria, fungi and mammalian systems

[1] . The coour

grence of co- has caused failures of many cases of genetic engineering, but the mecha-

nism of co-suppression may reveal some very interesting aspects of gene regulation. Therefore, it draws the interest of many biologists. Nuclear run-on assays indicated that co-suppression occurred after the transcription of the transgene, and it was then called post-transcriptional gene si-. Some hypotheses were proposed for the mechanisms of co-suppression, such lencing, PTGS as the threshold and RNA-dependent RNA polymerase (RdRp) hypothesis

can lead to Petunia hybrida Introduction of genes associated with pigment synthesis into chsA gene. Chalcone synthase is a key enzyme in the co-suppression, as is seen in the case of pathway of anthocyanin biosynthesis. Suppression of chalcone synthase expression in transgenic chsA transgenes therefore leads to losses of transformed with sense or anti-sense Petunia hybrida anthocyanin pigment on petals, and the flower alters from purple to white or purple with white sectors [1,2,4] . Due to the visibility of the flower pigmentation, the transgenic petunia becomes a

ChsA gene is transcriptionally activated in the epinice model system for co-suppression study. dermal cells of flower petals during the flower development in wild petunia chsA occurs in transgenic petunia, will it be limited to certain development peco-suppression of

riod of flowers or will it also occur in other tissues of other periods of the development? To ad-

dress these questions, we fused the

-glucuronidase (

uidA) gene to the C-terminal of

chsA gene,

[9 t 11] . When

cloned into a plant expression vector with a CaMV 35S promoter, and transferred the chimerical

gene into chsA-uidA

Petunia hybrida

via Agrobacterium tumefaciens.

By GUS histochemical lo-

calization and RNA

hybridization, we studied the co-suppression in different periods of the

development.

1 Materials and methods

1.1 Materials and reagents

E. coli strain DH5

and Agrobacterium tumefactions strain LBA4404 were stored in our lab.

Plasmid pBI121 was product of Clontech.

Petunia hybrida

"pure pink" was one of our collections.

DIG RNA labeling kit, anti-Dig AP were the products of Roche. Other chemicals were Sigma products or analytically pure reagents made in China.

1.2 Construction of expression plasmid

chsA coding sequence was amplified by PCR with two primers of CHS The complete

Xba I

(5 -CC TCT AGA AAA ATG GTG ACA GTC GAG GAG TAT CGT-3

) to introduce a

Xba I site

upstream of the translation start codon and CHS

BamH I (5 -AC GGA TCC AGC AAC ACT GTG

GAG GAC AAC AGT-3

) to delete the termination codon and introduce a

BamH I enzyme diges-

tion site. Plasmid pBI121-chsA was constructed by inserting the PCR fragment downstream of the CaMV 35S promoter and fused with open reading frame. Plasmid pBI121 was used as a control (fig. 1).

Xha I and BamH I digested chsA uidAgene in the same

diameter, and immersed in Agrobacterium for 5 min, then transferred to an MS agar plate supplemented with BA 1 mg/L, IAA 0.01 mg/L. Transformants were selected by 100 mg/L kanamycin, new seedling differentiated. Then media changed to MS media with antibiotic but no hormone.

1.4 Southern blot analyses

Total DNA was prepared from leaves using the method of hexadecyltrimethylammonium ∞L bromide (CTAB). About 0.5 to 1.0 g leaves were ground in liquid nitrogen, and then 500 CTAB buffer (2% CTAB, 1.4 mol/L NaCl, 0.2% mercaptoethanol, 20 mmol/L EDTA pH8.0, 100 g HCl pH8.0) was added and mixed with the liquid. After incubated in water bath at mmol/L Tris 1). 65 for 30 min, DNA was extracted by equal volume of chloroform: isoamyl alcohol (24 h g/min for 3 min. The supernatant was transferred into a The mixture was centrifuged at 5000 new tube and equal volume isopropanol was added. The genomic DNA was centrifuged at 10000 h g/min for 10 min and the pellet was washed with 70% ethanol and air dried. The DNA pellet . 10 cg plant DNA samples were digested with restric-_ 20 was resuspended in TE and stored at [12] tion enzymes, electrophoresed in a 0.8% agarose gel, and blotted according to Sambrook et al. chsA, uidA and Npt II were used as the probes. Radioac-To avoid the disturbance of endogenous

tively labeled probes were generated by the random prime method.

1.5 Northern blot analyses

DIG-11-dUTP labeled

Total RNA was extracted from leaves and flower buds using the method of guanidine thiocyanate-phenyl-chloroform. Northern blot was carried out according to Sambrook et al.

chsA cDNA fragment and DIG-11-dUTP labeled

cDNA fragment

[12]

were used as probes. Hybridization temperature was 68

1.6 GUS histochemical staining

GUS histochemical staining was performed according to Jefferson et al.

Fresh plant mate-

rials were incubated in the staining solution at 37

for 2 ü 30 h, bleached in 70% alcohol until

the materials became white. The staining solution contained 100 mmol/L NaPO

4, pH 7.0; 10

mmol/L EDTA pH 8.0; 0.1% Triton X-100; 1.0 mmol/L X-Gluc, stored at

-20

uidA

1.7 RNA hybridization in situ

> hybridization was carried out according to Cox et al. RNA in situ

Paraffin embedded tis-

sues were cut into 10

∞m sections. After being baked at 180

over night, slides were treated with

m/v). poly-1-lysine (0.1%,

DIG-labeled RNA probes were performed following the protocol of Roche RNA labeling kit.

ChsA gene was cloned in vector pGEM(7zf+) and digested either at the 5

end to obtain the or 3

sense chsA RNA or the antisense

chsA RNA.

The sections were dewaxed by xylenes and hydrated in a series of diluted ethanol (from

100% ethanol to H

2 O). After digested by proteinase K at 37

for 30 min, the sections were de-

Page 4

2 Results

2.1 Generating transgenic plants and Southern blotting analysis

To study the co-suppression in transgenic petunia, we constructed a plant expression plasmid chsA and uidA gene was transferred into and uidA gene (fig. 1). The fused carrying a fused Agrobacterium tumefaciens -mediated transformation of leaf discs. via Petunia hybrida Co-suppression occurred in about 20 transgenic petunia plant and the flower was changed from purple to white or white and purple. For the Southern blotting analysis of the transgenic petunia plant, uidA and Npt II were used as the probes to avoid the disturbance of endogenous chsA gene. Eco R I and Hin d III or both of them. Hybridization results showed Genome DNA was digested by that the target genes were integrated into the genome of transformed petunia plants in more than one copy (fig. 2).

Fig. 2. Southern blot analysis of DNA from transgenic petunia. Southern blot analysis of samples CG1 and CG3 are presented. Genomic DNA was digested with Eco RI(E), Hin dIII(H) or both of them (E,H). /Hin d III was used as DNA marker. were used as probes.

2.2 Northern blotting analysis of transgenic plants

0 3 cm) of the untransformed The total RNA was extracted from leaves and flower buds (2 petunia, transgenic petunia plant and the white part and purple part of fully opened flowers of chsA -uidA transgenic petunia plant. DIG-11-dUTP labeled cDNA fragment was used as chsA probe to perform Northern blotting (fig. 3). In lines 3 and 4, there were weak hybridization signals.

chsA gene had a very low expression. Therefore the It showed that co-suppression had started and corollas of the flowers showed a type of white in purple. Neither the white part nor the purple part of the fully opened flowers of transgenic petunia showed any hybridization signal. We also did another Northern blotting using samples of total RNA extracted from leaves of untransformed pechsA -uidA transformed petunia plant (before flowering) and leaves of uidA tunia plant, leaves of uidA cDNA transformed petunia plant (as control) to confirm the result. DIG-11-dUTP labeled fragment was used as probe (lines 8, 9,10 in fig. 3). Line 10 detected uidA gene, and line 9 detected chsA -uidA fused gene.

Fig. 3. Northern blot analysis of transgenic petunia. Line 1 was total RNA extracted from flower buds of the untransformed petunia. Line 2 was total RNA extracted from leaves of the untransformed petunia. Line 3 was total RNA extracted from flower buds of transgenic petunia. Line 4 was total RNA extracted from leaves of transgenic petunia. Line 5 was total RNA extracted from the white part of the flowers of transgenic petunia. Line 6 was total RNA extracted from the purple part of the flowers of transgenic petunia. Line 7 was total RNA extracted from leaves of transgenic petunia (after flower fully opened). Line 8 was total RNA extracted from leaves of the untransformed petunia. Line 9 was total RNA extracted from leaves of chsA-uidA transformed petunia (before flowwidA transformed petunia (as control). 28S rRNA was ering), and line 10 was total RNA extracted from leaves of used as control of loading quantity.

2.3 Time course of co-suppression in transgenic plants

chsA by and uidA genes were fused together, we could detect the expression of Because chsA uidA gene. Different organs (root, leaf, stem) of transgenic petunia detection of the expression of were histostained by X-Gluc before flowering. All of them could be dyed into blue before floweru 3). In addition, different lines showed different degrees of blue. According to ing (Plate I-1

Page 6

666

SCIENCE IN CHINA (Series C)

Vol. 44

Koes's method of dividing flower developing stage ^[9], we histostained different stages of the petunia flower (Plate I-5). At the developing early stage of the flower, sepal, stamen, little corolla could be dyed into blue. With the development of flower, the color became paled to colorless. At the same time the other organs could not be dyed either.

2.4 Localization of co-suppression by RNA

in situ hybridization

The different organs of flowered transgenic and wild petunia were sampled and prepared for paraffin slides and hybridized by using DIG labeled in vitro transcripts of chsA gene. As shown in Plate II, 1, 4, 7, 9 were the hybridization results of leaf, stem, root, corolla of the transgenic petunia, and signals could be detected in all the cells of both the nucleus and cytoplasm using chsA RNA as the probe (Plate II-2, 5, 8 and 10). While in wild petunia, signals could only be detected in inner and upper epidermal cells of corolla using chsA antisense transcripts probe (Plate II-3, 6, 11, 12).

3 Discussion

Biologists have made great efforts to study the mechanism of co-suppression in recent years.

The results showed that the copy number, DNA methylation and structure of the integrated T-DNA of the transgene may play a role in the process of co-suppression.

[67] The results also showed that RNA-dependent RNA polymerase may be involved in the RNA degradation.

[15,16] In the study of signal transduction, small signal molecules such as small RNA molecules were detected.

[17] In this research, we address this question from the aspects of localization of RNA degradation and co-suppression regarding plant development.

In this research, a fuse gene including chsA and uidA was transferred into petunia. Compared with wild petunia, the flower color of transformed petunia changed. Southern blotting showed that the T-DNA in transformed petunia was all multi-copy, and some inserting type was in a version of reverse repeat. Jorgensen et al.'s research revealed similar result, but they got both single and multi-copy intergrations, and the co-suppression rate was 25%

[18] In this research the security of the was 100%. We suggested that in all transgenic petunia we obtained multi-copy insertion, especially reverse repeat may play an important role in the occurrence of co-suppression.

In GUS histochemical localization experiments, the results showed that no co-suppression
happened before flowering, while no GUS staining in the plant after flowering. During the period
of flowering, the GUS staining became gradually pale. This may suggest that co-suppression happened during the flowering, which is consistent with the expression of endogenous

chsA in the
flower development. The results also indicated that the occurrence of co-suppression needs the
mutual interaction of endogenous and transgenic gene

chsA, this interaction is not in the level of
DNA-DNA, and it needs the transcription activity of endogenous

chsA. When co-suppression happened, no GUS staining was observed in the whole plant, which indicated that co-suppression
happened in the whole plant and was not restricted to the inner and upper epidemal layers of co-

Page 7

No. 6

CO-SUPPRESSION IN TRANSGENIC

Petunia hybrida

EXPRESSING

gene was expressed specifically. When co-suppression occurred rolla in which endogenous in flower during the development, co-suppression took place in other tissues too. These results suggested that there was a signal which might be transported from flower to other part of the plant.

Voinnet et al. found that there was a small RNA signal molecule with a size of 25nt involved in

GFP transformed and silenced tobacco

complex together with RNA helicase

. Hamilton detected 21

ü 25 nt small RNA molecule in

. Hammond detected small RNA molecules in drosophila gene silenced plants

[21] . In our chsA

transformed petunia, the small RNA signal molecules may also be involved.

In situ hybridization with RNA showed that there was no tissue specificity in co-suppression And it also showed that no signal could be detected with the sense RNA transcripts as a chsA RNA in the silenced cells. In the reprobe, which indicated that there was no free antisense

search of Zamore, there were mRNA and dsRNA when RNA was degraded, but dsRNA was in a

. Our results showed that there was mRNA. More work

needed to be carried out in detecting if there is dsRNA involved. Our results also showed that

RNA was degraded in cytoplasm, because signals could be detected in both nucleus and cytoplasm.

This result was consistent with the research on RNA-dependent virus resistance

[24]

Taken together, our results revealed the development feature of co-suppression and the localization of co-suppression. The process of co-suppression in

chsA transgenic petunia may be as-

sumed to be like the following process. In transgenic petunis plant,

chsA transgene was transferred

and inserted into petunia genome. When endogenous

chsA gene began to transcribe, some aberrant

RNA may be produced owing to the action of repeat segment of insertion. The aberrant RNA or part of it may act as signal molecules or the template of RdRp (belonging to plant

) to synthe-

size complement RNA (cRNA). The cRNA may be then annealed with mRNA, and was degraded

by double-stranded RNA specific RNase. The degradation of RNA would occur in cytoplasm. Fur-

ther experiments deep into the process are needed.
